

Name: KWASHI ELORM FREMA

Student ID: 22397307

Team name: SEG26-33 Meraki Arts

Project title: Meraki Arts Africa Website

Individual IA8 repository URL:

<https://github.com/Elorm07/dcit208-individual-assignments.git>

Team project repository URL: <https://github.com/Dept-of-Comp-Sci-University-of-Ghana/dcit208-client-project-2026-team-engineering-repository-seg26-33-merakiartsafrica.git>

Related PR URL: Not available because the Event Registration feature has not yet been implemented or submitted as a feature pull request.

B. Feature and deployment context= Selected feature: Event Registration

Requirement/story= The system should allow visitors to register for upcoming Meraki Arts Africa events.

User story= As a visitor, I want to register for an upcoming event so that I can participate in Meraki Arts Africa activities.

Deployment status= Still local . This is because the feature has not yet been implemented and deployed. The deployment plan is to first implement the frontend registration form and backend registration endpoint, connect the backend to the database, test the feature locally, configure the required environment variables, deploy the frontend and backend, and then perform smoke tests on the deployed version.

C. Environment and configuration table

Configuration item	Example placeholder	Secret?	Purpose
DATABASE_URL	mongodb://<placeholder>	Yes	Database connection
JWT_SECRET	<placeholder-secret>	Yes	Authentication/session security
API_BASE_URL	https://<backend-placeholder>	No	Backend API address
PORT	5000	No	Backend server port
FRONTEND_URL	https://<frontend-placeholder>	No	Frontend application URL
NODE_ENV	production	No	Runtime environment

D. Personal hand-drawn deployment sketch

E. Deployment steps

- Clone the team repository.
- Install the required dependencies.
- Configure the required environment variables using placeholder/local values.
- Set up the MongoDB database.
- Start the backend locally.
- Start the frontend locally.
- Test Event Registration locally.
- Run the project's lint and test commands.
- Push the completed implementation to GitHub.
- Deploy the frontend to the selected frontend hosting platform.
- Deploy the backend to the selected backend hosting platform.
- Configure the production environment variables on the hosting platforms.
- Update the frontend API URL to point to the deployed backend.
- Perform the smoke tests.
- Record the deployment URL and deployment evidence once the feature is actually deployed.

Current deployment URL= Not available because the feature has not yet been deployed.

F. Smoke-test checklist

The following smoke tests will be performed after the Event Registration feature is deployed.

Since the feature has not yet been deployed, no deployed smoke-test results are being claimed.

- Valid registration with synthetic participant data
- Invalid or missing registration information
- Duplicate registration for the same event
- Registration when the event has reached capacity
- Unauthorized access to registration information
- Backend or database failure during registration

Current status= Not yet performed because the feature has not been deployed. These checks will be performed after deployment.

G. Failure and rollback walkthrough

Failure= Backend deployment fails or the deployed frontend cannot communicate with the backend.

Symptom= The website loads, but submitting the Event Registration form produces an error or fails to create a registration.

Likely causes:

- Incorrect API_BASE_URL.
- Missing production environment variable.
- Backend deployment failed.

Evidence to check:

- Hosting/deployment logs.
- Backend application logs.
- Browser developer-console errors.

Immediate response= Check the deployment logs and verify the environment variables and backend URL. Do not expose any secrets while investigating.

Rollback/corrective action= If the latest deployment introduced the problem, revert to the last known working commit/deployment. Correct the configuration or code and redeploy.

Recovery confirmation= Open the deployed website, submit valid synthetic registration data, verify that the request reaches the backend and that the registration is stored successfully.

H. Release evidence

Because the feature has not yet been implemented, there is currently **no valid release evidence** to claim.

Use:

- GitHub tag: Not available
- Release note: Not available
- Commit hash: Not available for the completed feature
- PR link: Not available
- CI evidence: Not yet meaningful for this feature
- Team release documentation: Not available

Once the feature is implemented, I would replace these with the actual tag, commit, PR, CI result, and release documentation.

I. Operations and handoff note

The Event Registration feature should be monitored using backend application logs and deployment-platform logs.

Errors involving failed registration requests, database connections, and API requests should be recorded for troubleshooting.

A health check should confirm that the backend API is running and able to communicate with the database.

Database backups should be maintained to prevent loss of registration records.

Important limitations currently include the fact that Event Registration has not yet been implemented or deployed.

Before release, the team should complete implementation, configure production environment variables, test the feature, verify database connectivity, and perform the smoke-test checklist.

J. Oral defence video link= <https://youtu.be/udbepJ8RzE>

K. AI disclosure = AI was used to assist with organizing and wording parts of this deployment documentation. It helped structure the deployment plan, environment and configuration information, smoke-test scenarios, failure-handling process, rollback procedure, and oral defence script. I personally reviewed and verified the technical information included in this document, including the project repositories, selected Event Registration feature, current deployment status, technology stack, configuration requirements, and planned deployment process. I also ensured that no real secrets, passwords, API keys, or sensitive credentials were included. AI was not allowed to invent deployment evidence, claim that the feature had been implemented or deployed when it had not, create false GitHub commits, PRs, release tags, CI results, smoke-test results, or deployment URLs. Any evidence stated as unavailable reflects the actual current project status. The final responsibility for the accuracy of the submitted documentation and technical decisions remains mine.
